INHALTSÜBERSICHT

Einleitung	5
§ 1. Die Genauigkeit der Örter und Eigenbewegungen	5
§ 2. Der Katalog	10

Einleitung

In einer vorhergehenden Abhandlung aus dem Jahre 1935 über den „Geschwindigkeitskörper der Schwerpunktsbewegungen der Doppelsterne des nördlichen Himmels“ (Abhandlungen der Bayerischen Akademie der Wissenschaften, mathematisch-naturwissenschaftliche Abteilung, Neue Folge, Heft 31, 1935) habe ich als Grundlage der Untersuchung eine Zusammenstellung der Eigenbewegungen und ihrer Positionswinkel von 3800 Doppelsternen des nördlichen Himmels bekannt gegeben. Mit der Ableitung der Eigenbewegungen war notwendig eine Ableitung der Örter und der äquatorealen Komponenten der Eigenbewegungen verbunden, die nunmehr in der folgenden Abhandlung zusammengestellt sind, um weiteren praktischen Bedürfnissen und stellarstatistischen Untersuchungen als Basis zu dienen.

Wie bereits in der soeben genannten Abhandlung dargelegt ist, bildete das umfangreiche Material der „Geschichte des Fixsternhimmels“ der Preußischen Akademie der Wissenschaften die wesentliche Basis für die Ableitung der Örter und der E.B.-Komponenten. Das Material wurde aber darüber hinaus durch die neueren Kataloge bis zur Gegenwart (1934) ergänzt, da die Epochen der Örter der „G. F. H.“ nur bis zum Anfange dieses Jahrhunderts reichen. Da der „Preliminary General Catalogue“ von Boss ebenfalls nur bis zum Anfange des Jahrhunderts reicht, wurden die in diesem Kataloge enthaltenen Doppelsternörter und E.B. neugerechnet, wenn seitdem eine Reihe neuerer Örter vorlag. Dasselbe gilt gegenüber dem „Catalog of 4683 Stars for the Epoch 1900“ von Smith-Porter in Nr. 19 der „Publications of the Cincinnati Observatory“. Teilweise sind auch Stromsterne tabuliert worden, wenn sie auch für die Apex- und Vertexbestimmung keine Verwendung gefunden haben.

Die Berechnung der Örter und E.B.-Komponenten erfolgte nach der Methode der kleinsten Quadrate. Als Nullpunkt des Äquinoktiums und der Epoche wurde der Moment 1875 gewählt, weil einmal die Örter der „G. F. H.“ alle auf das Äquinoktium 1875 bezogen sind und ferner das Epochenmittel allgemein nahe bei 1875 gelegen ist, wie aus den Epochenangaben im unten folgenden Kataloge zu ersehen ist.

§ 1. Die Genauigkeit der Örter und E. B.

Die Berechnung der Genauigkeit der Örter und der E.B.-Komponenten beruht auf den folgenden Erwägungen. Die neueren Meridianbeobachtungen der Doppelsterne erhielten aus den schon in der früheren Abhandlung auseinandergesetzten Gründen kein höheres Gewicht gegenüber den älteren Messungen. Das Gewicht eines Doppelstern-Katalogortes wurde nur nach der Zahl der Einzelmessungen gestaffelt, wobei nur zur Bequemlichkeit der Rechnung einem auf 10 Einzelbeobachtungen beruhenden Katalogorte das willkürliche Gewicht 1 erteilt wurde; die wirklich vorkommende Anzahl der Einzelbeobachtungen liegt zwischen 2 und 6, so daß das Mittel bei 4 gelegen ist, so daß die Gewichtsunterschiede der Katalogörter bei demselben Stern meist keine großen Differenzen gegen den Mittelwert 0.4 erreichen. Katalogörter, die nur auf einer einzigen Beobachtung beruhen, wurden meist gestrichen, und solche, die ausnahmsweise auf mehr als 10 Einzelmessungen beruhen, behielten das Gewicht 1, im Einklange mit der Erfahrung, daß eine größere Zahl von Einzelmessungen am Meridiankreise die Genauigkeit des Mittels tatsächlich nicht mehr zu erhöhen vermag. Die im Interesse der Genauigkeit gelegene Anbringung von systematischen Korrekturen an die einzelnen Katalogörter geschah nur bei Vorhandensein von 5 und weniger als 5 Katalogörtern, um dadurch bei zu wenigen Katalogen und deshalb mit meist geringeren Epochendifferenzen verbundenen Örtern eine sichere E.B. zu gewährleisten. Bei mehr als 5 Örtern wurde allgemein auf eine Anbringung von Korrekturen verzichtet, außer in Einzelfällen bei auffallend irregulär schwankenden Örtern grade von Doppelsternen. Eine allgemeine Anbringung der Korrekturen war besonders deshalb nicht ratsam, weil für die neueren Kataloge noch keine systematischen Verbesserungen bekannt sind, zumal in bezug auf die Doppelsterne, also eine einseitige Anbringung an die älteren Örter allein zu vermeiden war. Es ist zu hoffen, daß später eine allgemeine Verbesserung möglich sein wird, sobald der neue A.-G. und andere Kataloge sowie die zur Zeit in Arbeit befindlichen amerikanischen Kataloge vorliegen werden. Dafür wird die vorliegende erstmalige Ableitung der Eigenbewegungen von Nutzen sein. Vorläufig ist das Mittel aus den älteren und zum Teil neueren Fundamentalkatalogen als das Bezugssystem des vorliegenden Kataloges anzusehen.

Die numerische Genauigkeit der Örter und E.B.-Komponenten wurde wie folgt abgeleitet. Wohl wurden für jeden einzelnen Doppelstern die mittleren Fehler des Ortes wie der E.B.-Komponenten in beiden Koordinaten nach der Methode der kleinsten Quadrate ermittelt, ebenso wie der mittlere Fehler einer Gleichung vom Gewicht 1. Im Generalkataloge ist aber davon abgesehen worden, die individuellen Fehler $\varepsilon(\alpha)$, $\varepsilon(\delta)$, $\varepsilon(\mu_\alpha)$ und $\varepsilon(\mu_\delta)$ anzugeben, wie es in manchen der neueren Kataloge geschehen ist; denn der mittlere Fehler einer Gleichung ist von Stern zu Stern derartig schwankend, in A.R. zwischen ± 0.010 und ± 0.100 , in Dekl. zwischen 0.10 und ± 1.00 , zumal bei der im allgemeinen nur mäßigen Anzahl von Gleichungen, d. h. Katalogörtern für den einzelnen Stern, daß die Angabe des individuellen Fehlers jedes einzelnen Sterns kein richtiges Bild der Fehler vermittelt und deshalb besser zu vermeiden ist. Ich halte es für zweckmäßiger, auf Grund des aus dem ganzen Material errechneten mittleren Fehlers einer Gleichung vom Gewicht 1 den entsprechenden durchschnittlichen mittleren Fehler der Unbekannten, d. h. der Örter der Epoche und der E.B.-Komponenten, gruppenweise nach der Deklination geordnet, als Funktion der Epochendifferenz bei jedem Stern und der Anzahl der benutzten Kataloge d. h. Gleichungen zu bestimmen. Dafür ist die Annahme eines Modells von Gleichungen notwendig, das bei einer größeren Zahl von Gleichungen den Beobachtungen entspricht. Es möge angenommen werden, daß bezüglich der Verteilung der einzelnen Kataloge über die Epochendifferenz bei jedem Stern eine zeitlich gleichmäßige Verteilung stattfindet; zugleich möge das Gewicht aller Gleichungen 1 sein. Aus den Koeffizienten der Unbekannten ist dann nach den Prinzipien der Methode der kleinsten Quadrate das Gewicht der Unbekannten zu ermitteln; der aus dem ganzen Material schon bekannte mittlere Fehler ε einer Gleichung vom Gewicht 1 vermittelt dann den mittleren Fehler der Unbekannten. Die angenommene symmetrische Verteilung der Beobachtungen bewirkt, daß der mittlere Fehler der Unbekannten ein Minimum, die Gewichte also ein Maximum werden, zumal auch jeder Gleichung das Höchstgewicht 1 erteilt wurde. Gegenüber der Wirklichkeit stellen diese Fehler also die untere Grenze dar, die von der Wirklichkeit nicht unterschritten werden kann.

Es seien k Katalogörter eines Sterns, also k Gleichungen vorgelegt, verteilt über die Epochendifferenz t , so daß t in $k-1$ gleiche Teile $r = \frac{t}{k-1}$ zerlegt sei. Das Mittel aller Epochen der einzelnen Kataloge sei t_0 , und α_0 und δ_0 die entsprechenden Koordinaten in A.R. und Deklination; die Geschwindigkeitskomponenten derselben seien $\alpha'_0 = \mu_\alpha$ und $\delta'_0 = \mu_\delta$. Bei einer ungeraden Zahl k von Gleichungen entspricht dem Mittelwert t_0 eine Gleichung, die gerade in der Mitte liegende Gleichung, nicht aber bei geradem k , weshalb die Rechnung zuerst für ein ungerades k ausgeführt werde. Ist t_i ein beliebiger der k Zeitpunkte, so lautet die allgemeine Gleichung:

$$(1) \quad \alpha_0 + (t_i - t_0) \alpha'_0 = b_i, \quad i = 1, 2, \dots, k,$$

wo b_i die beobachtete A.R. angibt. Mit Rücksicht auf unsere Einteilung der Epochendifferenz t lauten die Bedingungsgleichungen dann wie folgt:

$$(2) \quad \left\{ \begin{array}{l} \alpha_0 - \frac{1}{2}(k-1)r \alpha'_0 = b_1 \\ \alpha_0 - \frac{1}{2}(k-3)r \alpha'_0 = b_2 \\ \text{-----} \\ \alpha_0 - \frac{1}{2} \cdot 2 \cdot r \alpha'_0 = b_{\frac{1}{2}(k-1)} \\ \alpha_0 = b_{\frac{1}{2}(k+1)} \\ \alpha_0 + \frac{1}{2} \cdot 2 \cdot r \alpha'_0 = b_{\frac{1}{2}(k+3)} \\ \text{-----} \\ \alpha_0 + \frac{1}{2}(k-3)r \alpha'_0 = b_{k-1} \\ \alpha_0 + \frac{1}{2}(k-1)r \alpha'_0 = b_k \end{array} \right.$$

Die Anwendung der Methode der kleinsten Quadrate ergibt dann die beiden Normalgleichungen

$$(3) \quad \begin{cases} k \cdot \alpha_0 = (b)_1 \\ \frac{1}{2} t^2 \cdot S \cdot \alpha'_0 = (b)_2 \end{cases}$$

wo die rechten Seiten mit $(b)_1$ und $(b)_2$ für die Gewichtbestimmung gleichgültig sind und wo der Faktor

$$S = (k-1)^2 + (k-3)^2 + \dots + 4^2 + 2^2 = \frac{1}{6} k (k^2 - 1).$$

Dabei sei vermerkt, daß die 1. Gleichung auch bei nicht gleichmäßiger Verteilung der Beobachtungen über die Epochendifferenz gilt. Infolge der im vorliegenden Falle besonders einfachen Form der Normalgleichungen werden die Gewichte von α_0 und α'_0 unmittelbar gleich ihren Koeffizienten in den beiden Normalgleichungen, also:

$$(4) \quad p(\alpha_0) = k \text{ und } p(\alpha'_0) = \frac{1}{12} t^2 k (k^2 - 1) = \frac{1}{12} t^2 \frac{k(k+1)}{k-1}.$$

Ist k eine grade Zahl, so ergibt sich genau dieselbe Formel. Das Gewicht von α_0 ist nur bei der Wahl des Zeitpunktes t_0 als Mittel aller Epochen in einfachster Weise gleich der Zahl k der Gleichungen; hätte man für t_0 etwa die Grenzepochen t_1 oder t_k gewählt, so würde sich für den diesen Epochen entsprechenden Wert von α_0 das Gewicht

$$(5) \quad p_1(\alpha_0) = \frac{1}{2} \frac{k(k+1)}{2k-1}$$

ergeben haben; das Gewicht p_1 ist kleiner als p ; bei $k = \text{Minimum} = 3$ ist $p_1(\alpha_0) = 1.2$, $p(\alpha_0) = 3$; $k = 4$ ergibt $p_1(\alpha_0) = 1.43$, $p(\alpha_0) = 4$. Bei wachsendem k konvergiert $p_1(\alpha_0)$ gegen $\frac{1}{4}k = \frac{1}{4}p(\alpha_0)$, so daß der entsprechende mittlere Fehler von ε_1 gegen den doppelten Fehler von ε konvergiert. Dagegen ergibt sich für $p(\alpha'_0)$ in beiden Fällen dieselbe Formel, so daß auch die mittleren Fehler bei beiden Methoden dieselben Werte behalten, was plausibel ist, da α'_0 nur eine relative Größe, die zeitliche Änderung von α_0 , ist. Da nun $p(\alpha'_0)$ proportional t^2 ist, so daß der mittlere Fehler von α'_0 umgekehrt proportional t ist, so wird, wenn ε der mittlere Fehler der Gewichtseinheit:

$$(6) \quad \varepsilon(\alpha'_0) = \frac{\varepsilon}{\sqrt{p(\alpha'_0)}} = \frac{\varepsilon}{t} \sqrt{\frac{12(k-1)}{k(k+1)}} \text{ und } \varepsilon(\alpha_0) = \frac{\varepsilon}{\sqrt{p(\alpha_0)}} = \frac{\varepsilon}{\sqrt{k}}.$$

Mit wachsendem k wird also $\varepsilon(\alpha'_0)$ umgekehrt proportional $\sqrt{k}$, und das Verhältnis der Gewichte:

$$(7) \quad \frac{p(\alpha'_0)}{p(\alpha_0)} = \frac{1}{12} t^2 \frac{k+1}{k-1}$$

konvergiert mit wachsendem k gegen $\frac{1}{12} t^2$, somit auch das Verhältnis der mittleren Fehler

$$(8) \quad \frac{\varepsilon(\alpha_0)}{\varepsilon(\alpha'_0)} = \frac{1}{6} \sqrt{3} t \sqrt{\frac{k+1}{k-1}}$$

gegen $\frac{1}{6} \sqrt{3} t = 0.289 t$, Kontrollformeln, die von den unten folgenden Tabellen erfüllt werden.

Der Fall $k = 2$ fällt nicht unter die obigen Formeln der Ausgleichung, weil 2 Unbekannte vorhanden sind. Liegen nur 2 Katalogörter vor, so ergibt sich aber der mittlere Fehler von α_0 und α'_0 wie folgt. Da die beiden Gleichungen in diesem Falle

$$\begin{cases} \alpha_0 + t_1 \alpha'_0 = b_1 \\ \alpha_0 + t_2 \alpha'_0 = b_2 \end{cases}$$

und die Lösung $\alpha'_0 = \frac{b_2 - b_1}{t_2 - t_1}$ ist, so ist, da $\varepsilon(b_1) = \varepsilon(b_2) = \varepsilon =$ mittlerer aus dem Gesamtmaterial bekannter Fehler einer Gleichung vom Gewicht 1: $\varepsilon(\alpha'_0) = \frac{\sqrt{2}}{t_2 - t_1} \varepsilon$, also das Gewicht von α'_0 : $p(\alpha'_0) = \frac{1}{2} (t_2 - t_1)^2$.

Wird t_1 , also auch α_0 , auf das Mittel der Zeiten t_1 und t_2 bezogen, so daß $\alpha_0 = \frac{1}{2} (b_1 + b_2)$, so wird:

$\varepsilon(\alpha_0) = \frac{1}{2} \sqrt{2} \varepsilon$; entspräche α_0 dagegen dem Zeitpunkt t_1 oder t_2 , so würde $\varepsilon_1(\alpha_0) = \varepsilon$; im ersten Falle ist

das Gewicht von α_0 : $p(\alpha_0) = 2$, im zweiten Falle: $p_1(\alpha_0) = 1$; auch hier also $p_1(\alpha_0) < p(\alpha_0)$. Würde man in die obigen allgemeinen Formeln den Wert $k = 2$ substituieren, so erhielte man trotz des Ausnahmefalles $k = 2$ doch auch die soeben abgeleiteten Werte für $p(\alpha_0)$ und $p_1(\alpha_0)$. Alle Formeln gelten in gleicher Weise für die Deklination.

Die Anwendung der abgeleiteten Formeln auf unseren Doppelsternkatalog gestaltet sich dann folgendermaßen.

Aus dem Gesamtmaterial der Doppelsterne wurden je 200 Sterne je Deklinationszone 0 — 5° usw. (s. die folgende Tabelle) herausgegriffen; dann wurden die folgenden mittleren Fehler je Gleichung vom Gewicht 1 erhalten:

Tabelle 1

δ	ε_α	ε_δ
0	ε	ε
0—5	± 0.036	± 0.40
5—15	0.27	32
15—30	0.32	40
30—40	0.29	32
40—49	0.36	39
49—56	0.50	40
56—65	0.48	43
65—75	1.02	58
75—85	1.46	43

Während ε_δ wesentlich konstant bleibt und im Mittel ± 0.41 beträgt, steigt ε_α naturgemäß proportional $\sec \delta$, vielleicht noch in geringer Abhängigkeit von anderen Faktoren, die speziell bei Doppelsternen eine Rolle spielen; die Ausgleichung in A.R. nach der Formel $\varepsilon_\alpha = \varepsilon_0 \sec \delta$ ergibt: $\varepsilon_0 = \pm 0.027$ und zwar gültig für die dem Gewicht 1 entsprechende Zahl von 10 Einzelbeobachtungen eines Katalogortes. Da aber, wie wir oben schon bemerkten, ein Katalogort im Mittel aus nur 4 Einzelbeobachtungen besteht, so erhalten wir den wirklich stattfindenden durchschnittlichen m. F. einer Gleichung mittels Division von ε_α und ε_δ durch $\sqrt{0.4}$, so daß der tatsächliche m. F. einer Gleichung: $\varepsilon_\alpha = \bar{\varepsilon} \sec \delta$, wo $\bar{\varepsilon} = \pm 0.0426 = \pm 0.639$ und $\varepsilon_\delta = \pm 0.646$, so daß sehr nahe $\bar{\varepsilon} = \varepsilon_\delta = \pm 0.64$. Mithin ergibt sich zunächst für den von der Anzahl k abhängigen durchschnittlichen m. F. $\varepsilon(\delta_0)$ einer Deklination in dem unten folgenden Generalkatalog die Tabelle 2:

Tabelle 2. M. F. einer Katal.-Dekl.

k	$\varepsilon(\delta_0)$	k	$\varepsilon(\delta_0)$
2	± 0.46	9	± 0.22
3	37	10	20
4	32	12	19
5	29	14	17
6	26	16	16
7	24	18	15
8	23	20	14

Analog ergibt sich für den durchschnittlichen m. F. einer Katalog-Rektaszension in unserem Generalkataloge in Abhängigkeit von k und δ die weitere Tabelle 3:

Tabelle 3. M. F. einer Katal.-A.R.

$\delta \backslash \delta_0$	2	3	4	5	6	7	8	9	10	12	14	16	18	20
0	s	s	s	s	s	s	s	s	s	s	s	s	s	s
0	± 0.030	± 0.025	± 0.022	± 0.019	± 0.018	± 0.016	± 0.015	± 0.014	± 0.014	± 0.012	± 0.012	± 0.011	± 0.010	± 0.010
10	31	25	22	20	18	16	15	14	14	13	12	11	10	10
20	32	26	23	20	19	17	16	15	14	13	12	11	11	10
30	35	28	25	22	20	19	18	16	16	14	13	12	12	11
40	40	32	28	25	23	21	20	19	18	16	15	14	13	12
50	47	38	33	30	27	25	24	22	21	19	18	17	16	15
60	61	50	43	39	35	33	30	29	27	25	23	21	20	19
70	89	72	63	56	52	48	44	42	40	36	34	31	30	28
80	175	143	124	111	102	94	88	82	78	71	66	62	58	55

Was nun die mittleren Fehler der E.B.-Komponenten anbetrifft, so möge zunächst der Faktor f von t^2 in dem Ausdruck für $\frac{1}{t^2} p(\alpha'_0)$ bzw. $\frac{1}{t^2} p(\delta'_0)$ tabuliert werden, zumal er für manche anderweitige analoge Untersuchungen gebraucht werden kann, als Funktion von k , also $f = \frac{1}{12} \frac{k(k+1)}{k-1}$ (bei großem k nahe $= \frac{1}{12} k$):

Tabelle 4. $f = \frac{1}{t^2} p(\alpha'_0)$.

k	f	k	f
2	0.500	9	0.938
3	0.500	10	1.019
4	0.556	12	1.182
5	0.625	14	1.346
6	0.700	16	1.511
7	0.778	18	1.676
8	0.857	20	1.842

Um nun den m. F. einer E.B. zu berechnen mittels

$$\varepsilon(\alpha'_0) = \frac{\bar{\varepsilon} \sec \delta}{\sqrt{\frac{1}{t^2} p(\alpha'_0)}} \quad \text{bzw.} \quad \varepsilon(\delta'_0) = \frac{\varepsilon_\delta}{\sqrt{\frac{1}{t^2} p(\delta'_0)}}$$

$$= \frac{1}{t} \frac{\bar{\varepsilon} \sec \delta}{\sqrt{f}} \quad = \frac{1}{t} \frac{\varepsilon_\delta}{\sqrt{f}}$$

ist die Zwischenzeit t der Epochen bei jedem einzelnen Doppelstern zu berücksichtigen. Bei kleinem k bleibt die E.B. immer stark unsicher und nur für größere Werte von k hat die Fehlerbetrachtung der E.B. überhaupt einen Sinn; dann aber erstreckt sich das Zeitintervall t der Beobachtungsepochen über die Zeit von W. Struves „Positiones mediae“ bis zur Jetztzeit, so daß im Durchschnitt von 1825 bis 1925, mit der mittleren Epoche 1875, also für grade rund ein Jahrhundert Epochendifferenz Beobachtungen der öfter gemessenen Sterne vorliegen. Deshalb erhält man ein einigermaßen zutreffendes Bild der Genauigkeit der E.B. unserer Doppelsterne im Generalkatalog, wenn rund $t = 1$ gesetzt wird (die E.B.-Komponenten sind für ein Jahrhundert angesetzt worden). Dann aber ergeben sich die mittleren Fehler $\varepsilon(\alpha'_0)$ und $\varepsilon(\delta'_0)$ mittels f in der soeben aufgestellten Tabelle 4, die für $t = 1$ direkt das Gewicht von α'_0 und δ'_0 fixiert, und mit Hilfe der mittleren Fehler einer Gleichung in α und δ aus den folgenden Tabellen 5 und 6:

Tabelle 5. M. F. der saek. E. B. in Dekl.

k	$\varepsilon(\delta'_0)$	k	$\varepsilon(\delta'_0)$
2	± 0.91	9	± 0.67
3	91	10	64
4	86	12	59
5	82	14	56
6	77	16	52
7	73	18	50
8	70	20	48

Tabelle 6. $\varepsilon(\alpha'_0) =$ m. F. der saek. E. B. in A. R.

$\delta \backslash k$	2	3	4	5	6	7	8	9	10	12	14	16	18	20
0°	± 0.06	± 0.06	± 0.06	± 0.05	± 0.05	± 0.05	± 0.05	± 0.04	± 0.04	± 0.04	± 0.04	± 0.04	± 0.03	± 0.03
10	7	6	6	6	5	5	4	5	4	4	4	4	3	3
20	6	6	6	6	6	5	5	5	4	4	4	4	4	3

70	18	18	17	16	15	14	14	13	12	12	11	10	10	9
80	35	35	33	31	30	28	27	26	24	23	21	20	19	18

Im weiter unten folgenden Generalkatalog ist die Anzahl k der benutzten Kataloge in der letzten Kolumne, getrennt für α_0 und δ_0 , aufgeführt, so daß der durchschnittliche m. F. der Örter wie der E.B.-Komponenten mit k bzw. k und δ als Argument aus den obigen Tabellen entnommen werden kann.

§ 2. Der Katalog.

Dem Kataloge mögen folgende Erklärungen beigegeben werden.

Die Kolumne 1 enthält die laufende Nummer der Doppelsterne gemäß Burnhams „General Catalogue of Double Stars“, nach dessen Numerierung für das Äquinoktium für 1880 unser Katalog für 1875 als Äquinoktium wie Epoche angeordnet geblieben ist, wenn auch einige Sterne durch Präzessionswirkung oder E.B. der Rektaszension nach umgestellt werden müßten. Die in Burnhams Appendix ab Nr. 12756 aufgeführten zusätzlichen Doppelsterne sind in die zugehörige Stelle der A.R. eingeschoben worden.

Kolumne 2 enthält nötigenfalls die Angabe der Komponente: A, B, C usw. oder p = praec., s = sequ., ma = major, mi = min., med. = media oder GB $\equiv$ Gesamtbild, sobald eine Bemerkung erforderlich war, um etwaige Verwechslungen zu vermeiden.

Kolumne 3 enthält die Angabe der Größen, woraus allgemein die Rangordnung der Komponenten nach der Größe zu erkennen ist, sobald alle Komponenten tabuliert sind. Ist, wie meist, nur eine Komponente des Doppelsterns beobachtet bzw. tabuliert, so bezieht sich der angegebene Ort immer auf den Hauptstern, wenn neben der Größenangabe keine Bemerkung in der Kolumne 2 enthalten ist. Die Größenangaben sind Aitkens „New General Catalogue“, also dem Draper-Kataloge, bei hier fehlender Angabe der „G. F. H.“ entnommen, oder den Angaben in Schlesingers „Bright Stars“, insbesondere bei allen in dem „Preliminary General Catalogue“ von Boss enthaltenen Doppelsternen. Alle Größenangaben sind eingeklammert, wenn sie nicht dem Draper-Kataloge entstammen. Auch bei den „media“-Örtern bezieht sich die Größenangabe immer auf den Hauptstern.

Kolumne 4 enthält die A.R. für das Äquin. und die Epoche 1875, unter Verwendung der in der 7. Kolumne enthaltenen E.B.-Komponente. Wo es möglich war, sind auch die durch die Meridianbeobachtungen erhaltenen A.R. der Komponenten angegeben. Bei unsicherer E.B. kann es vorkommen, daß bei der Reduktion der Örter auf die angenommene Epoche 1875 eine ursprüngliche p-Komponente zur s-Komponente werden kann, ebenso wie dadurch eine positio borealis zu einer positio australis werden kann, und umgekehrt.

Kolumne 5 enthält die jährliche Präzession in A. R. nach O. Struve, da die Örter der „G. F. H.“ bereits mit dieser Konstanten behandelt worden sind. Der eventuelle Übergang auf die Newcombsche Konstante wird zweckmäßig mittels der Tafeln der Hamburger Sternwarte bewerkstelligt.

Kolumne 6 enthält die Variatio saecularis in A. R.

Kolumne 7 enthält die 100jährige E.B. in A.R., berechnet bis auf 0^o01. Die Angabe 0.00 bedeutet, daß die E.B.-Komponente innerhalb der Epochendifferenz der Beobachtungen des Sterns verschwindend klein ist; ein frei gelassener Raum in Kolumne 7, ebenso wie in der Kolumne 11 der E.B. in Deklination, bedeutet, daß die E.B.-Komponente infolge zu geringer Epochendifferenz oder infolge zu starken Schwankens der verschiedenen Katalogörter, besonders bei geringer Anzahl der letzteren, nicht angebbar ist.

Kolumne 8 enthält die Deklination für das Äquin. und die Epoche 1875, unter Verwendung der in der 11. Kolumne enthaltenen E.B.-Komponente. Im übrigen gilt hier das bereits unter der Kolumne 4 Gesagte.

Kolumne 9 enthält die jährliche Präzession in Deklination nach O. Struve.

Kolumne 10 enthält die Variatio saecularis in Dekl.

Kolumne 11 enthält die 100jährige E.B. in Deklination, berechnet bis auf 0^o1. Im übrigen gilt hier das schon für Kolumne 7 Gesagte. Weiteres s. unter Kolumne 12.

Kolumne 12 enthält im allgemeinen die unter Berücksichtigung der Gewichte der einzelnen Katalogörter jedes Sterns berechnete mittlere Epoche der benutzten Katalogörter, um mittels des gegebenen Ortes und der E.B. einen von der berechneten E.B. unabhängigen Ort wiederherstellen zu können, wenn es in Zukunft nötig sein sollte. Die Jahrhundertzahl der Epoche ist fortgelassen, da die mittleren Epochen wesentlich um 1875 gelegen sind und nur zwischen 1840 und 1930 überhaupt vorkommen, so daß kein Zweifel über die Jahrhundertzahl entstehen kann. Bei einer Reihe von Sternen liegt außer nur einem A.G.-Katalog-Ort neuerdings ev. nur noch ein in den beiden Yale-Katalogen: „Transactions of the Astronomical Observatory of Yale University“, Vol. 7, + 55^o to + 60^o (1930), und Vol. 9, + 25^o to 30^o, enthaltener Ort vor; alsdann wurde dieser Yale-Ort nebst der zugehörigen Epoche und E.B. nach Yale angegeben. Bei den schon im „P. G. C.“ von Boss vorkommenden Sternen wurde die entsprechende Nummer des „P. G. C.“ in Kolumne 12 eingetragen und deshalb im übrigen außer der E.B. des „P. G. C.“ nur noch die Zeitminute der A.R. und der Grad der Deklination angegeben. Dasselbe gilt für die Sterne, die in dem eingangs erwähnten Kataloge Nr. 19 des Cincinnati Observatory vorkommen. Bei den wenigen dem Hamburger E.B.-Lexikon entnommenen Doppelsternen ist immer auch die B.D.-Nummer angegeben worden, ebenso wie bei den Sternen, die dem Schlesingerschen Kataloge der „Bright Stars“ und damit Porters Katalog in Nr. 18 der Cincinnati Publications entnommen wurden, nicht aber Boss-Sterne sind. Dementsprechend bedeutet in Kolumne 12: B = Boss P. G. C., Ci = Cincinnati 19, H = Hamburger E.B.-Lexikon, S = Schlesingers „Bright Stars“, S 7 und S 9 Schlesingers oben genannte Zonen. Sind diese Bezeichnungen

in Kolumne 12 eingeklammert, so bedeutet dies eine Neurechnung von Ort und E.B. auf Grund der Hinzuziehung neuerer Beobachtungen, worauf möglichst gesehen wurde.

Kolumne 13 enthält die Anzahl k der für beide Koordinaten des Sterns benutzten Kataloge; eine einzige Zahl bedeutet die Gleichheit der Zahl k für beide Koordinaten.

Kolumne 14 gibt die B.D.-Nummer jedes Sterns bzw. auch jeder Komponente, falls ihr eine besondere B.D.-Nummer zukommt. Das Vorzeichen $+$ oder $-$ vor der Nummer bedeutet, daß die Gradangabe der Deklination um ± 1 zu ändern ist, um die richtige B.D.-Nummer zu erhalten.

Der 2. Teil des Kataloges, der die A.-R.-Stunden 12–24^h bringen wird, wird in Kürze dem vorliegenden Kataloge folgen.

Zum Schluß ist es mir eine Freude, meiner Mitarbeiterin an der Aufstellung des Kataloges, meiner Tochter Gerda Wilkens, für die unter stets gleichbleibendem Eifer ausgeführte treue Mitarbeit meinen herzlichsten Dank auszusprechen.
